## nag\_zunmhr (f08nuc)

### 1 Purpose

nag\_zunmhr (f08nuc) multiplies an arbitrary complex matrix  $C$  by the complex unitary matrix  $Q$  which was determined by nag\_zgehrd (f08nsc) when reducing a complex general matrix to Hessenberg form.

### 2 Specification

```
#include <nag.h>
#include <nagf08.h>
void nag_zunmhr (Nag_OrderType order, Nag_SideType side,
                  Nag_TransType trans, Integer m, Integer n, Integer ilo, Integer ihi,
                  const Complex a[], Integer pda, const Complex tau[], Complex c[],
                  Integer pdc, NagError *fail)
```

### 3 Description

nag\_zunmhr (f08nuc) is intended to be used following a call to nag\_zgehrd (f08nsc), which reduces a complex general matrix  $A$  to upper Hessenberg form  $H$  by a unitary similarity transformation:  $A = QHQ^H$ . nag\_zgehrd (f08nsc) represents the matrix  $Q$  as a product of  $i_{\text{hi}} - i_{\text{lo}}$  elementary reflectors. Here  $i_{\text{lo}}$  and  $i_{\text{hi}}$  are values determined by nag\_zgebal (f08nvc) when balancing the matrix; if the matrix has not been balanced,  $i_{\text{lo}} = 1$  and  $i_{\text{hi}} = n$ .

This function may be used to form one of the matrix products

$$QC, Q^H C, CQ \text{ or } CQ^H,$$

overwriting the result on  $C$  (which may be any complex rectangular matrix).

A common application of this function is to transform a matrix  $V$  of eigenvectors of  $H$  to the matrix  $QV$  of eigenvectors of  $A$ .

## 8 Parallelism and Performance

`nag_zunmhr` (f08nuc) is threaded by NAG for parallel execution in multithreaded implementations of the NAG Library.

`nag_zunmhr` (f08nuc) makes calls to BLAS and/or LAPACK routines, which may be threaded within the vendor library used by this implementation. Consult the documentation for the vendor library for further information.

Please consult the x06 Chapter Introduction for information on how to control and interrogate the OpenMP environment used within this function. Please also consult the Users' Note for your implementation for any additional implementation-specific information.

## 9 Further Comments

The total number of real floating-point operations is approximately  $8nq^2$  if **side** = Nag\_LeftSide and  $8mq^2$  if **side** = Nag\_RightSide, where  $q = i_{\text{hi}} - i_{\text{lo}}$ .

The real analogue of this function is `nag_dormhr` (f08ngc).

## 10 Example

This example computes all the eigenvalues of the matrix  $A$ , where

$$A = \begin{pmatrix} -3.97 - 5.04i & -4.11 + 3.70i & -0.34 + 1.01i & 1.29 - 0.86i \\ 0.34 - 1.50i & 1.52 - 0.43i & 1.88 - 5.38i & 3.36 + 0.65i \\ 3.31 - 3.85i & 2.50 + 3.45i & 0.88 - 1.08i & 0.64 - 1.48i \\ -1.10 + 0.82i & 1.81 - 1.59i & 3.25 + 1.33i & 1.57 - 3.44i \end{pmatrix},$$

and those eigenvectors which correspond to eigenvalues  $\lambda$  such that  $\text{Re}(\lambda) < 0$ . Here  $A$  is general and must first be reduced to upper Hessenberg form  $H$  by nag\_zgehrd (f08nsc). The program then calls nag\_zhseqr (f08psc) to compute the eigenvalues, and nag\_zhsein (f08pxc) to compute the required eigenvectors of  $H$  by inverse iteration. Finally nag\_zunmhr (f08nuc) is called to transform the eigenvectors of  $H$  back to eigenvectors of the original matrix  $A$ .
