

NAG Library Function Document

nag_search_vector (m01fsc)

1 Purpose

nag_search_vector (m01fsc) searches a vector of arbitrary type data objects for the first or last match to a given value.

2 Specification

```
#include <nag.h>
#include <nagm01.h>
Nag_Boolean nag_search_vector (Pointer key, const Pointer vec, size_t n,
                               ptrdiff_t stride,
                               Integer (*compare)(const Nag_Pointer a, const Nag_Pointer b),
                               Nag_SortOrder order, Nag_SearchMatch final, Pointer *match,
                               NagError *fail)
```

3 Description

nag_search_vector (m01fsc) searches a sorted vector of n arbitrary type data objects, which are stored in the elements of an array at intervals of length **stride**. **vec** must have previously been sorted into the specified order.

The function searches for the first or last match depending on the value of **final**. It returns Nag_TRUE if an exact match is found and **match** is set to point at that object. If there is no exact match then Nag_FALSE is returned and **match** is set to point to either the next later element, if **final** = Nag_First, or the next earlier element, if **final** = Nag_Last.

4 References

None.

5 Arguments

- | | | |
|----|--|--------------|
| 1: | key – Pointer | <i>Input</i> |
| | <i>On entry</i> : the object to search for. | |
| 2: | vec[n] – const Pointer | <i>Input</i> |
| | <i>On entry</i> : the array of objects to be searched. | |
| 3: | n – size_t | <i>Input</i> |
| | <i>On entry</i> : the number n of objects to be searched. | |
| | <i>Constraint</i> : $0 \leq n \leq \text{MAX_LENGTH}$, where MAX_LENGTH is an implementation-dependent value for the maximum size of an array. | |
| 4: | stride – ptrdiff_t | <i>Input</i> |
| | <i>On entry</i> : the increment between data items in vec to be searched. | |

Note: if **stride** is positive, **vec** should point at the first data object; otherwise **vec** should point at the last data object.

Constraint: $0 < |\text{stride}| \leq p$, where p is an implementation-dependent value for the maximum `size_t` size on the system, divided by **n** if **n** is positive.

- 5: **compare** – function, supplied by the user *External Function*

`nag_search_vector` (m01fsc) compares two data objects. If its arguments are pointers to a structure, this function must allow for the offset of the data field in the structure (if it is not the first).

The function must return:

- 1 if the first data field is less than the second,
- 0 if the first data field is equal to the second,
- 1 if the first data field is greater than the second.

The specification of **compare** is:

```
Integer compare (const Nag_Pointer a, const Nag_Pointer b)
```

1: **a** – const Nag_Pointer *Input*

On entry: the first data field.

2: **b** – const Nag_Pointer *Input*

On entry: the second data field.

- 6: **order** – Nag_SortOrder *Input*

On entry: specifies whether the array will be sorted into ascending or descending order.

Constraint: **order** = Nag_Ascending or Nag_Descending.

- 7: **final** – Nag_SearchMatch *Input*

On entry: specifies whether to search for the first or last match. This also determines the pointer returned if an exact match cannot be found.

Constraint: **final** = Nag_First or Nag_Last.

- 8: **match** – Pointer * *Output*

On exit: if an exact match is found this is a pointer to a pointer to the matching data object. If an exact match is not found this is set to point to the nearest object. If **final** = Nag_First this is the next later element, otherwise the next earlier element.

- 9: **fail** – NagError * *Input/Output*

The NAG error argument (see Section 2.7 in How to Use the NAG Library and its Documentation).

6 Error Indicators and Warnings

NE_BAD_PARAM

On entry, argument **final** had an illegal value.

On entry, argument **order** had an illegal value.

NE_INT_ARG_EQ

On entry, **stride** = $\langle value \rangle$.
 Constraint: **stride** $\neq 0$.

NE_INT_ARG_GT

On entry, **n** = $\langle value \rangle$.
 Constraint: **n** $\leq \langle value \rangle$, an implementation-dependent size that is printed in the error message.
 On entry, **stride** = $\langle value \rangle$.
 Constraint: $|\text{stride}| \leq \langle value \rangle$, an implementation-dependent size that is printed in the error message.

NE_INT_ARG_LT

On entry, **n** = $\langle value \rangle$.
 Constraint: **n** ≥ 0 .

7 Accuracy

Not applicable.

8 Parallelism and Performance

`nag_search_vector` (m01fsc) is not threaded in any implementation.

9 Further Comments

The maximum time taken by the function is approximately proportional to $\log_2 n$.

10 Example

The example program reads a key and a list of real numbers, which have been sorted into ascending order. It then searches the list for the first number which matches the key.
